Summary

Black holes are astrophysical objects with gravitational fields so extreme that they bend even the trajectories of light. Specifically, in the geometrical optics limit, the paths of particles and fields moving at the speed of light follow null geodesics in the curved spacetime geometry. Consequently, the presence of a black hole can lead to strong lensing effects on the images emerging from their surroundings. Additionally, the passage of light through the gravitational field leads to changes in the frequency and intensity of the light, which is particularly important to understand the observational imprints of accretion disks forming around black holes.

BlackHoleImages is a Wolfram Mathematica packet designed to compute the aforementioned effects in the field of isolated rotating black holes in Einstein's General Relativity, which are known as the Kerr family of spacetimes. The packet can be used for computing:

- photon orbits (null geodesics) in the fields of black holes,
- generating images of stellar backgrounds distorted by black holes, and
- generating images of accretion disks near black holes.

The packet contains three packages, `KerrNullGeodesics`, `AlphaDiskModel`, and `KerrImages`. `KerrNullGeodesics` implements the analytical solutions for null geodesics in Kerr space-times as described in detail by Gralla & Lupsasca (2020). The `AlphaDiskModel` then implements the standard α -disk model for the accretion disk near a black hole as proposed by Shakura & Sunyaev (1973), specifically its relativistic incarnation by Novikov & Thorne (1973) and Page & Thorne (1974). Finally, the `KerrImages` package uses the previous two packages to provide functions that compute the disk images and the lensed images of faraway backgrounds.

We expect this packet to be used primarily for investigating the observational characteristics of accretion disks of black holes, including dynamical processes in the disk, since the time delay of each geodesic is also computable in this packet. The packet can also be used for educational purposes, such as plotting null geodesics in the Kerr metric or illustrating the lensing effects, or for any other purpose where the computation of photon trajectories is necessary.

Statement of need

Black holes are one of the most intriguing objects in modern physics. They were one of the earliest predictions of Einstein's general relativity and started to be indirectly through observations in various electromagnetic bands starting from the 1960s (Narayan & McClintock, 2015). Since most observations were and still are unable to resolve the spatial scales of the so-called event horizon of the black hole, we need to understand the radiation that emerges from the interactions of the black hole with its surroundings and the emergent spectrum. This was provided by the seminal α accretion disk model of Shakura & Sunyaev (1973) and Novikov

40 & Thorne (1973). As a result, the community of astronomers and astrophysicists identified
41 the first candidates for black holes in the Universe.

42 Currently, the evidence for dark compact objects consistent with black holes is overwhelming.
43 Throughout the 1990s, two teams of astronomers followed stars orbiting very close to our
44 Galactic center and deduced on the presence of a dark compact object with the mass of¹
45 $4 \cdot 10^6 M_{\odot}$ (Genzel et al., 2010; Ghez & others, 2008); the leaders of the teams later shared
46 the 2020 Nobel prize in physics (Nobel Prize Outreach, 2020). In 2015, the LIGO collaboration
47 detected the first merger of black holes by gravitational waves (LIGO and Virgo collaborations,
48 2016) and more than 180 events were detected to date (LVK Collaboration, 2025). In 2017,
49 the Event Horizon Telescope collaboration reconstructed the image of the accretion flow in the
50 immediate vicinity of the massive black hole in the center of the M87 galaxy by the methods
51 of very long baseline interferometry (Event Horizon Telescope collaboration, 2019a). They
52 followed up this result in 2020 by presenting a similar image of the accretion flow from the
53 center of our very own Galaxy the Milky Way (Event Horizon Telescope collaboration, 2022).

54 The images of the massive black holes from M87 and the Milky Way present a dark feature
55 in their centers known as the “shadow” of the black hole. It corresponds to a region of the
56 sky where the paths of the photons are bent so much that they end behind the black hole
57 horizon, the point from beyond which not even light can escape. While this qualitative picture
58 is correct, the precise quantitative science inferred from the observations of the Event Horizon
59 Telescope requires the detailed modeling of the accretion flow, its radiation, and the emerging
60 photon orbits (Event Horizon Telescope collaboration, 2019b). This is one of the important
61 use cases our packet is aiming for.

62 Another important application of the packet is the interpretation of timing and spectral
63 features of unresolved accreting black holes as observed in the burgeoning field of time-domain
64 astronomy (Burns et al., 2025). Transients such as quasi-periodic eruptions, oscillations, or
65 outflows emerging from systems containing accreting black holes are detected at an increasing
66 rate. They often contain subtle timing features that require precise modelling of the accretion
67 flows and other physical components, but possibly also the lensing effects by the black holes.
68 Our packet can be easily extended to compute the lightcurves and/or images emerging from
69 these systems.

70 Last but not least, the topic of black holes captures the imagination of the public. In the
71 2014 movie *Interstellar* directed by Christopher Nolan, the general movie audience was able
72 to observe a faithful simulation of a black hole image for the first time (James et al., 2015).
73 Our packet provides an intermediate step for relativity students and other interested parties to
74 be able to dissect how such an image is made through a user-friendly Wolfram Mathematica
75 packet.

76 On the more technical side, this is also one of the first open source releases of an implementation
77 of the *analytical* solution for null geodesics in Kerr space-time (the only other implementation
78 we know of is (Omwoyo, 2025)). Other implementations typically use numerical differential
79 equation solvers (e.g. the EinsteinPy implementation (Shivotam & Bapat, 2020)). The
80 arbitrary precision capabilities of *Wolfram Mathematica* thus allow to use this packet as an
81 exact validation and reference solution for such machine precision codes. Using the symbolic
82 calculus capabilities of Mathematica provided a good platform to implement the relatively
83 complicated analytical solution as a starting point. The packet could now also be used as
84 a reference when porting the solutions to more optimized lower-level implementations. For
85 example, the Mathematica code *KerrGeodesics* (Warburton et al., 2023) for time-like geodesics
86 (trajectories of massive test particles) in Kerr space-time was recently rewritten in Python as
87 *KerrGeoPy* (Park & Nasipak, 2024), our packet could follow a similar route.
